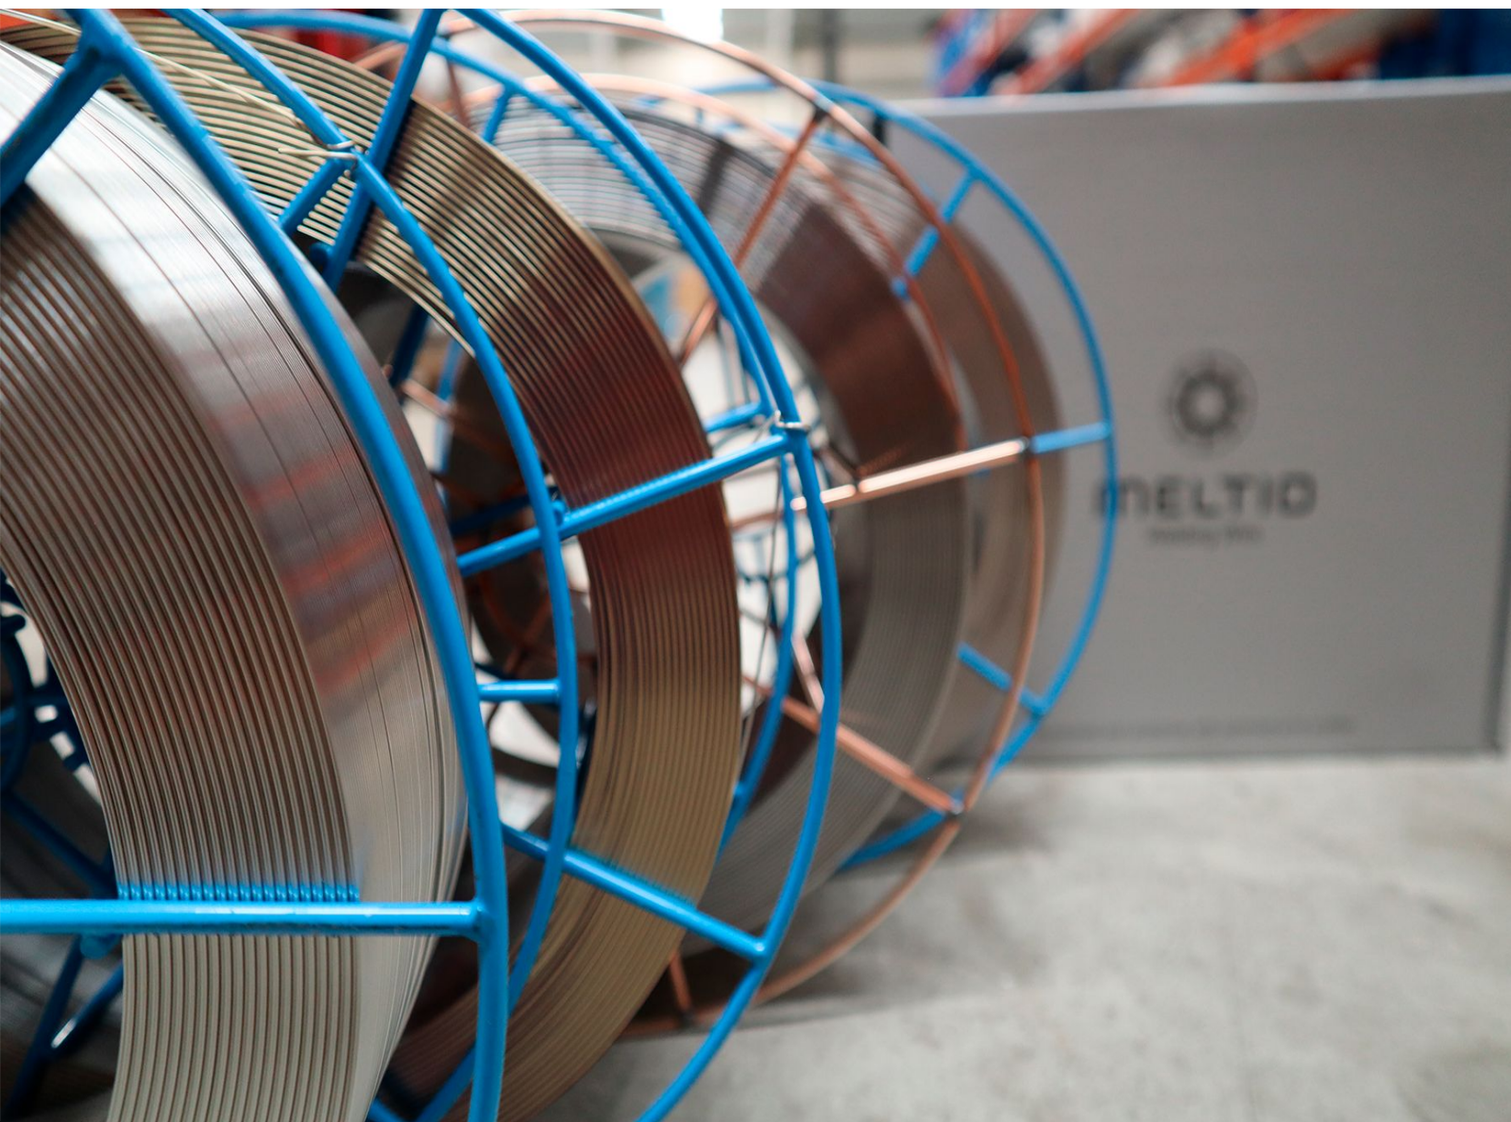
Meltio

# Materials Handbook

## V3.0 / August 2025



# Index

# Introduction

In recent years, **additive manufacturing (AM)**, also known as **3D printing**, has emerged as an innovative technology revolutionizing the manufacturing industry. This disruptive technique enables the creation of complex geometries and intricate designs that were previously unattainable through conventional manufacturing processes. One of the areas that has experienced the most significant advancements in additive manufacturing is the **production of metallic materials**.

Meltio's use of **metal wire as feedstock** has led to substantial improvements in deposition control, material waste reduction, enhanced operational safety, and broader compatibility with a wide range of metallic material families. This wire-based approach ensures a stable and reliable material flow, resulting in smoother and more consistent additive manufacturing processes.

By leveraging these advantages, Meltio has not only optimized its processes but also expanded the scope of additive manufacturing applications. This ongoing commitment to innovation and material development continues to unlock new possibilities and extend the capabilities of Meltio's technology, offering users a wide array of material options and parameterization tools for their additive manufacturing needs.

In this document, Meltio has compiled all internal knowledge and information regarding materials with the aim of sharing it with the community. Here, you will find a detailed overview of all tested materials, including their characterization and parameterization for Meltio machines. The document also includes guidance on **creation of print profiles, material characterization**, **post-processing**, **heat treatments**, and **dual-material printing recommendations**, among other key topics.

# Meltio Laser Head Specifications

| | Infrared | Blue | Blue (High Power Option) |
|---|---|---|---|
| Available in: | M450, Meltio Engine v2 & v3 | M600 & Meltio Engine Blue | Meltio Engine Blue |
| Laser power (Total / Per diode or Fiber) | 1200W / 6 x 200W | 1000W / 9 x 120W | 1400W / 9 x 160W |
| Beam Shape | Matrix beam, Circular | Matrix Beam, rectangular | Matrix Beam, rectangular |
| Energy Distribution | Polar array of 6 beams approximating a top-hat energy distribution within the spot. | Polar array of 9 beams approximating a top-hat energy distribution within the spot. | Polar array of 9 beams approximating a top-hat energy distribution within the spot. |

# The Nature of Laser

**L**ight **A**mplification by **S**timulated **E**mission of **R**adiation.

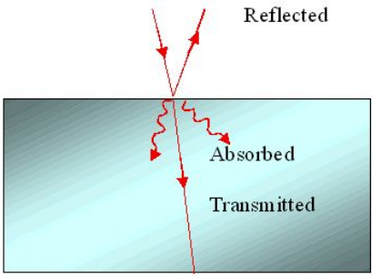
Meltio's blue **multi-laser approach is cost-effective**, outperforming expensive single high-power blue lasers, while **improving energy efficiency and sustainability** over infrared

***Planck-Einstein Equation:***

$$E = h \cdot f = \frac{h \cdot c}{\lambda}$$

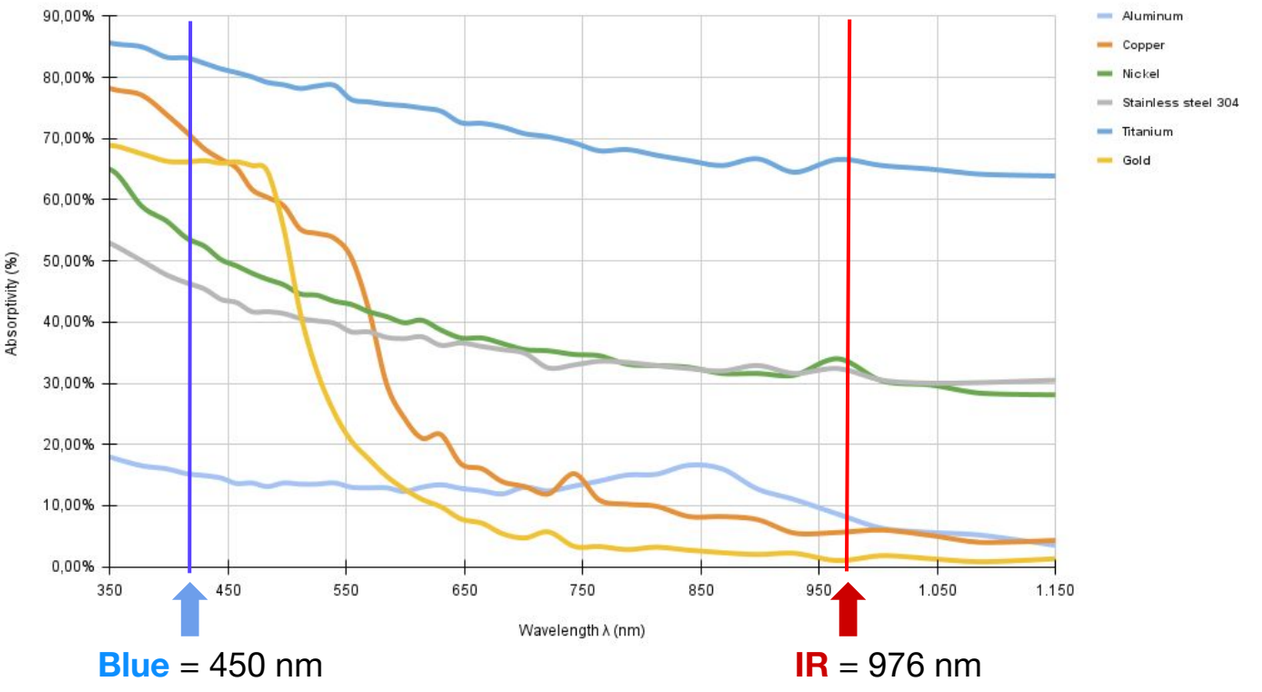
$$E_{976} = \frac{hc}{976 \times 10^{-9}} \approx 1.27\,\text{eV}$$

$$E_{450} = \frac{hc}{450 \times 10^{-9}} \approx 2.76\,\text{eV}$$



**Blue wavelength offer higher photon energy** which is **absorbed more efficiently by metals** compared to **Infrared.**

# Materials Absorptivity to different wavelengths



NASA TN D-5353, *Solar Absorptance and Spectral Reflectances of 12 Metals for Temperatures Ranging from 300 to 500 K*, E.W. Spisz, NASA Technical Note, Lewis Research Center, 1969. Available at: https://ntrs.nasa.gov/citations/19690024595

# Material Parametrization

Keep in mind that every material is different. Therefore, the procedure for specific materials may vary. This guide is a basic introduction on how to parametrize a new material for the Meltio Engine Blue and may be used as an initial point of reference.

### Considerations for Parameterization

There are a few things that should be considered about the new material to be parameterized.

●Will this material be able to absorb much energy from the laser beam of the Meltio Blue (450 nm wavelength)?

- Does it get oxidized really easily?
- What are the required mechanical properties?

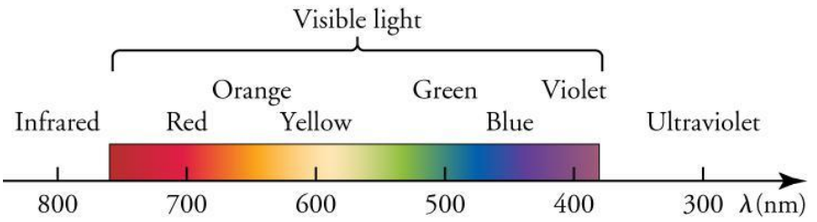


Figure 11.8. Electromagnetic spectrum.

# Material Printability

After testing more than 50 different materials of all the material families, Meltio determine that in most of the cases, an alloy is hard to print if it has:

- High carbon content (steels)
- High reflectivity of laser wavelength (i.e. copper for IR)
- Ceramic phases inside final microstructure
- High melting temperature (refractories)
- Affinity for oxidation (titanium and aluminum)
- High thermal conductivity (copper & aluminum)

Apart from this poisonous elements like lead or arsenic between others make the printing process not safe for the operator, so should also be considered, all standard Meltio Materials does not contain any poisonous element.

Resuming, the chart below summarize all the main properties that are involved inside material printability and their expected behaviour:

| **Material** | **Thermal Conductivity** Conducts heat away from the process, lower is better. | **Surface Reflectivity** Percentage of light reflected, lower is better. | **Electrical Conductivity** Relevant for hot wire, lower is better. | **Affinity to Oxidation** Affects shield gas consumption, lower is better. | **Affinity to Cracking*** Causes processing defects. Lower is better. Really depends on the alloy. | **Meltio Printability** |
|---|---|---|---|---|---|---|
| Stainless Steels | Low | Low | Very Low | Low | Low | Very Easy |
| Mild Steels | Low-Medium | Low-Medium | Low | Low-Medium | Very Low | Easy |
| Tool Steels | Low | Low-Medium | Low | Low-Medium | Medium-High | Medium |
| Nickel Alloys | Low | Low | Low | Very Low | Very Low | Very Easy |
| Titanium Alloys | Low | Low | Very Low | Very High | Medium | Medium |
| Copper Alloys | Very High | High | Very High | Medium | Low-Medium | Difficult |
| Aluminum Alloys | High | Very High | High | High | High | Difficult |

* *Laser welding processes such as Meltio have lower heat input and hence are less prone to produce cracks and defects in the part.*

# Open Platform and Meltio Materials

Meltio's **Laser Metal Deposition (LMD) technology** is built on an **open material platform**, allowing customers to use **readily available welding wire** to achieve outstanding mechanical performance. In any case Meltio can supply any material, ask for the **Official List of Available Materials** to your sales representative.

While **Meltio Materials** represent the **pre-validated and fully parameterized** alloys we offer, our **technology is not limited to them**. Customers and partners can **develop and optimize new materials** to gain a **competitive advantage** in their industries.

Our process delivers **high-density parts (>99.97%)** with **superior mechanical properties**, while ensuring **zero material waste—100% of the deposited material is used in the final part**.

# Meltio Materials: Fully Validated & Optimized for LMD

Meltio offers a **portfolio of tested and validated materials**, available for purchase, **with ready-to-use parameters** in **Meltio Horizon** and **Meltio Space** slicing software.

**Key Benefits of Meltio Materials**

✔ **Turnkey Printing Experience** – Fully parameterized for **optimal print quality, efficiency, and reliability** on standard geometries.

✔ **High Material Efficiency** – **100% of extruded material is used in the part**, with **zero waste**.

✔ **Multi-Material Capabilities** – Print with **Single**, **Dual**, or **Quad-Wire** for advanced applications.

# Meltio Materials and Their Value Proposition

## Stainless Steels (AISI 316L, AISI 308L)

Stainless steel is a corrosion-resistant alloy composed mainly of iron, carbon, and chromium. It forms a protective chromium oxide layer that prevents rust and staining. With its durability and aesthetic appeal, stainless steel is widely used in various industries, including kitchenware, appliances, construction, and automotive components.

## Tool/Carbon Steels (AISI H11)

The three general categories are low, medium, and high carbon steel. More carbon means harder and stronger. Less carbon means cheaper, softer, and easier to produce.
Carbon steel is most commonly found as a structural building material, in simple mechanical components, and in various tools.

## Mild Steels (AWS ER70S-6)

It has low carbon content (<0.25% by wt.). It is ductile, machinable, and weldable. It is used in automobiles, furniture etc.

## Nickel Alloys (Nickel 718, Nickel 625)

Nickel is a versatile element and will alloy with most metals. Nickel alloys are alloys with nickel as principal element. Its high versatility, combined with its outstanding heat and corrosion resistance has led to its use in a diverse range of applications; such as Aircraft gas turbines, steam turbines in power plants and its extensive use in the energy and nuclear power markets.

## Titanium Alloys (Ti6Al4V)

It's really hard to refine. This is why this metal is so expensive. Its strength to weight ratio is higher than any other metal. This makes it extremely valuable for anything that flies. It's use where the weight requirements are critical and aluminum alloys cannot fit in.

## Copper Alloys (AWS ERCuNiAl and CuCrZr)

Common applications include electronics, water pipes, and giant statues that represent liberty. Copper will form an oxidized layer, that will prevent further corrosion. Essentially, it'll turn green and stop corroding. This can make it last for centuries.

## Aluminium Alloys (Al 4046)

Aluminum has amazing strength-to-weight ratio, this is the metal that's largely responsible for flight. It's easily formed (malleable)hile it doesn't rust, it will oxidize. Iron is the only metal that "rusts" by definition. Aluminum will corrode when it contacts salt. However, it will *not* corrode in contact with water.

# Meltio TRL Classification System

**Meltio can additive manufacture parts in metals such as copper and aluminum using its blue laser technology. However, for now, this technology works well only with thin-walled or small parts. When we try to print larger or solid parts, technical challenges arise**—mainly due to how these materials behave during heating and cooling. We are actively developing and improving the process to make it more reliable with these metals in larger formats.

To determine the development stage of each material, we use an international scale called the Technology Readiness Level (TRL), which ranges from 1 to 9 (from experimental to fully ready for industrial production).

Meltio has adapted this scale into an internal classification with four levels:

- **Meltio Explore (TRL 1–3):** Initial exploration phase. For R&D only.
- **Meltio Develop (TRL 4–6):** Validation of initial concepts and prototype testing, ongoing parameter improvement, and profile standardization.
- **Meltio Qualified (TRL 7–8):** Materials ready for demanding applications. High reliability.
- **Meltio Proven (TRL 9):** Fully validated for production. Final industrial use.

Copper and aluminum are currently between TRL 3 and 5, meaning they are in validation and optimization phases. In contrast, steels, nickel alloys, and titanium are already between TRL 7 and 9, which means they are successfully used in real-world applications.

| Meltio Materials | TRL |
|---|---|
| ER70S-6 | Qualified - Proven |
| SS316L | Qualified - Proven |
| SS308L | Qualified - Proven |
| 17-4Ph | Qualified |
| Nickel 718 | Qualified - Proven |
| Nickel 625 | Qualified |
| H11 | Qualified - Proven |
| Titanium Grade 5 | Qualified - Proven |
| ErCuNiAl | Develop |
| CuCrZr | Develop |
| Al 4046 | Develop |

# List of Tested Materials by Meltio

In the next section, Meltio has tried to summarize all the materials that were successful during the parametrization and characterization. All the materials are divided by material family, if the material is fully characterize or only tested with a few samples and if is available in Meltio material catalogue.

Meltio can supply any material, ask for the **Official List of Available Materials** .

**Always request availability of said material through Meltio**, we will provide the material in the shortest time or if it is not possible we will recommend the point of contact.

| Material | Material Family | Fully Characterized / Tested - IR Laser | Fully Characterized / Tested - Blue Laser | Availability |
|---|---|---|---|---|
| ER70S-6 | Mild Steel | Characterized | Characterized | Meltio material |
| SS316 | Austenitic Stainless Steel | Fully Characterized | Fully Characterized | Meltio material |
| SS307 | Austenitic Stainless Steel | Tested | Tested | Compatible |
| SS308 | Austenitic Stainless Steel | Tested | Fully Characterized | Meltio material |
| 17-4PH | Precipitation Hardening Stainless Steel | Fully Characterized | Fully Characterized | Meltio material |
| 1.4343 (SS309) | Austenitic Stainless Steel | Tested | Tested | Compatible |
| SS410 | Martensitic Stainless Steel | Tested | Tested | Compatible |
| SS410NiMo | Martensitic Stainless Steel | Tested | Tested | Compatible |
| SS420 | Martensitic Stainless Steel | Tested | Tested | Compatible |
| Super Duplex | Austenitic - Ferritic Stainless Steel | Tested | Tested | Compatible |
| 35N | Alloy Structural Steels | Tested | Tested | Compatible |
| Invar | Nickel Alloy | Fully Characterized | Tested | Compatible |
| Nitinol | Nickel Alloy | Tested | Tested | Compatible |
| Inconel 718 | Nickel Alloy | Fully Characterized | Fully Characterized | Meltio material |
| Inconel 625 | Nickel Alloy | Fully Characterized | Fully Characterized | Meltio material |
| Monel K500 | Nickel Alloy | Tested | Tested | Compatible |
| Hastelloy X | Nickel Alloy | Tested | Tested | Compatible |
| H11 | Tool Steel | Fully Characterized | Fully Characterized | Meltio material |
| H12 | Tool Steel | Tested | Tested | Compatible |
| H13 | Tool Steel | Tested | Tested | Compatible |
| P20 | Tool Steel | Tested | Tested | Compatible |
| M7 | Tool Steel | Tested | Tested | Compatible |
| Stellite | Cobalt Alloy | Tested | Tested | Compatible |
| Ti 553 | Titanium Alloy | Tested | Tested | Compatible |
| Titanium Grade 5 | Titanium Alloy | Fully Characterized | Fully Characterized | Meltio material |

# List of Tested Materials by Meltio (Continuation)

| Material | Material Family | Fully Characterized / Tested - IR Laser | Fully Characterized / Tested - Blue Laser | Availability |
|---|---|---|---|---|
| ERCuSi-A | Bronze | Tested | Tested | Compatible |
| Bronze Bearing | Bronze | Tested | Tested | Compatible |
| Bronze Marine (ErCuNiAl) | Bronze | Fully Characterized | Fully Characterized | Meltio material |
| CuCrZr | Copper | Tested | Tested | Meltio material |
| CuNi7 | Cupronickel | Tested | Tested | Compatible |
| CuNi30 | Cupronickel | Tested | Tested | Compatible |
| Babbit (Tin) | White Metal | Tested | Tested | Compatible |
| Pure Gold | Noble Metal | Tested | Tested | Compatible |
| White Gold | Noble Metal | Tested | Tested | Compatible |

| NICARW (Ni-CW composite) | Specialty | Tested | Tested | Compatible |
| Haynes 25 | Cobalt alloy | Tested | Tested | Compatible |

# Introduction to Meltio Material Datasheets

Material datasheets (https://meltio3d.com/materials/) are technical documents that provide detailed information on the properties, characteristics, and specifications of a particular material. These documents are an essential tool for engineers, designers, and manufacturers as they allow them to select the appropriate material for a specific application, evaluate its performance, and predict its behavior under different conditions of use.

Inside a datasheet, a customer should find detailed information about properties, characteristics and different specifications of the material. This datasheets will lead to a better understanding and better material selection for a specific application.

## Contents of Meltio Material Datasheets

### General Properties

Including general information on the material and the printing machinery, such as: wire diameter, spool weight, spool type, coating presence, melting point, material density, recommended build plate, recommended drive wheels, and the type of inertization required.

Ti64 is a popular and widely used alloy due to its excellent combination of strength, low density, and corrosion resistance. It is used in a variety of industries, including aerospace, and chemical processing, due to its properties. Its high strength-to-weight ratio makes it a preferred choice for lightweight applications.

General Properties

| Wire Diameter | Weight on Spool | Spool Type | Wire Coating | Melting Point | Wire Density | Recom. Build plate | Drive Wheels | Inertization[4] |
|---|---|---|---|---|---|---|---|---|
| 1.0 mm | 7.5 kg | BS300 | Uncoated | 1674 °C | 4.4g/cm³ | Titanium | 1.0 V-Groove | Full chamber |

### Chemical Properties

Consists of the chemical composition of the material. It lists all its alloys and their proportion. In addition to the chemical composition.

Chemical Composition

| Ti | Al | V | Fe | C | N | H | O |
|---|---|---|---|---|---|---|---|
| Bal. | 5.5 | 3.5 | 0.4 | 0.08 | 0.05 | 0.015 | 0.2 |

### Heat Treatment

It can be found a small text about the mandatory nature of the heat treatment followed by the main recommended steps to carry it out.

**Heat Treatment**

Heat treatment is recommended for Ti64 to enhance its mechanical properties. Through heat treatment, the alloy becomes stronger, more ductile, and more resistant to fatigue, making it suitable for high-stress applications. Heat treatment also eliminates residual stresses and helps to refine the microstructure of the alloy, leading to improved toughness and increased resistance to crack growth. Heat treatment of Ti64 after 3D printing is a crucial step in maximizing its performance in applications.

| Solution Annealing | | Age Hardening | |
|---|---|---|---|
| Vacuum atmosphere<br>Heat up to 920ºC | Hold for 2h<br>Cooling to RT | Vacuum atmosphere<br>Heat up to 460ºC | Hold for 8h<br>Cooling inside the oven to RT |

### Tested Print Profiles

A table of basic printing parameters that have demonstrated good performance on Meltio machines. It includes the material deposition rate, volume rate, relative density achieved with Meltio systems, and general data such as maximum pore size and observed defects.

Tested Print Profiles

| Laser | Profile name | Laser Power [W] | Energy Density [J/mm3] | Deposition Rate [g/h] | Volume rate [cc/h] | Relative Density [%] | Max Pore/Defect [µm] | Oxygen Content |
|---|---|---|---|---|---|---|---|---|
| 976 nm | Verified Density | 1100 | 122.22 | 143 | 32.5 | 99.90 | - | 0.250 - 0.450 |
| 450 nm | Rev 30 2024-12-17 | 1000 | 47.62 | 333 | 75.68 | 99.87 | 376 / 550 | 0.095 - 0.213 |

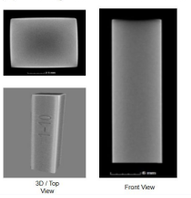
* Printing profiles available in our official Slicers: **Meltio Horizon** for standalone Printers and **Meltio Space** for Laser Integration Kits.

### Internal Structure

Ensure that the material meets industry requirements for density, microstructure, and absence of defects, all of which are critical for achieving optimal mechanical properties.

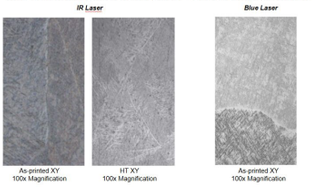
Tomography

CT Scan of 3D printed sample part in Ti64 using IR Laser without detectable voids or defects. Resolution of 24 µm per pixel.



Internal Structure [3]
Micrography

The observed microstructure is composed of acicular martensite embedded in the beta phase. The columnar shape of the grains extends along the manufacturing direction due to epitaxial growth of the original beta phase. In the XY section, the microstructure appears as polyhedral grains of α' + β, with alpha phases at grain boundaries.



### Structural Properties and Reference Standards

It shows all the values of mechanical properties obtained from the material, with a table to be able to make the **comparison with some casting and forging standards**. The aim is that the material approaches or even exceeds the standards of the sector.

Structural Properties [1]

| ASTM E8/E8M<br>UNE EN ISO 6892-1<br>UNE EN ISO 6507-1 | Wire | Infrared Laser | | | | Blue Laser | | | |
|---|---|---|---|---|---|---|---|---|---|

| Stress Ratio (R) | -1 | | | |

## Key Takeaways from Material Datasheets

**“Real” Materials**

With Meltio the material composition used for additive manufacturing is close to the commodity material used in the welding industry, not a special blend for AM.

**Density**

All our material test are targeted to find showcases with densities above 99.75%, up to **99.87%** for Titanium or **99.97%** for 316LSi.

This is as good as it gets in Metal AM, no other technology can beat us.

**Near Isotropy**

The Compact heat affected zone, high cooling rate and excellent densification lead to a uniform microstructure and high levels of isotropy.

Parts typically show less than 10% anisotropy in Ultimate tensile strength placing Meltios printing process at the leading edge of what is achievable in direct metal 3D Printing.

**Rivaling Traditional Mfg**

All of our tested material results in terms of mechanical properties are compared to casting and wrought.

All results are superior to casting and most of them are up to par with wrought, in accordance with the available base standard.

**Deposition Parameters**

Meltio provides a set of developed and validated process profiles, integrated into its own Slicers, which allow reproducible and high quality results to be obtained.

In addition all testing data comes referenced with the third party lab responsible for the analysis of the samples.

## Current Meltio Material Datasheets

**Meltio Stainless Steel 316L**

Highly corrosion-resistant grade of austenitic stainless steel with great mechanical properties. Ideal for marine and chemical applications.

**Meltio Titanium 64**

High strength Alpha+Beta alloy with excellent fracture toughness, corrosion resistance and biocompatibility. Widely used in aerospace, marine, chemical and biomedical industries.

**Meltio Stainless Steel 17-4PH**

A martensitic precipitation hardened stainless steel capable of achieving high hardness while offering excellent corrosion resistance. Typical applications include pump impellers, pipes, and valves.

**Meltio Nickel 718**

High strength nickel-super alloy with large working temperature range. Highly resistant against cracking while protecting well against corrosion.

**Meltio Mild Steel ER70S**

Mild steel with adequate mechanical properties and high ductility. Easily welded and machined.

**Meltio Nickel 625**

Ni625 excels for its weldability, making it an ideal choice for cladding or repair of components working at high temperatures or requiring increased corrosion protection.

**Meltio Tool Steel H11**

One of the most commonly used tool steels, thanks to its outstanding impact toughness. Widely used for hot tooling applications, in the manufacturing of dies, and in aerospace applications.

**Meltio Invar**

This alloy gets its name thanks to its extremely low coefficient of thermal expansion, from -250°C up to about 200° C. Ideal for measuring equipment, cryogenic applications and molds for composite components.

**Meltio CuCrZr**

High-performance copper alloy with excellent thermal and electrical conductivity, combined with enhanced mechanical strength thanks to chromium and zirconium additions. Ideal for heat exchangers, electrical components, and welding electrodes.

**Meltio Aluminun 4046**

Aluminum-silicon alloy with good corrosion resistance and excellent weldability. Commonly used as a filler metal or for components requiring thermal management and good surface finish.

**Meltio Marine Bronze (ERCuNiAl)**

Copper-nickel-aluminum alloy designed for high-strength applications in marine environments. Combines excellent corrosion resistance with good mechanical performance, making it suitable for shipbuilding, offshore components, and desalination equipment.

# Parametrization Steps for  High Density Parts With A Reliable Process

In order to achieve high density parts there are a few key requirements. The single most important requirement leads to the energy input per unit volume of material. Insufficient energy input will lead to pores and lack of fusion, which results in poor material performance, on the other hand excessive energy input will lead to unstable process and process control activations

The most relevant parameters for this study are: **Deposition Speed**, **Layer Height, Layer Width**, **Laser Power and Rotation angles and Process Control**. The energy density is not an input parameter, but rather a result between the extrusion width, layer height, print speed and laser power.  **Recommendation:** Always ensure the **wire feeder is properly tightened** to prevent deposition issues.

## Relevant Additive Manufacturing Parameters Configuration for Solid Profiles

### Laser Power

For all materials and configurations, the **laser power should be set to the maximum available** on the machine to achieve the **highest possible deposition rate**. The rest of the parameters will be optimized to ensure a reliable process.

### Layer Parameters for Solid Profiles

For printing solid profiles with the Meltio system, it is recommended to use the following layer parameter ranges to ensure optimum density and stability in the printing process:

- **Layer Height (LH):** 1.0 – 1.2 mm. Larger Layer Heights will make the material be out of the Machine Working Distance. Larger laser power allow larger layer heights.
- **Layer Width (LW):** 1.0 – 1.4 mm. Based on our experiments the layer width is always slightly larger than the LH, this will offer good adhesion between passes, using way larger LW can cause porosity between passes.

### Print Speed

Our focus is to reach the maximum energy density (Laser Power/ LH*LW*Print Speed) that allows a stable process, **a stable process means no Process Control Activations**. Usually lower Printing Speed and larger lh and LW allows higher concentrations of heat allowing higher deposition rates when compared to moving faster and smaller LH and LW. Different sets of Print Speeds are tested, after this cut with wire EDM and then evaluated through penetrant liquid test, the result with the highest deposition rate and less porosity is selected.

### Rotation angles

In the infrared system, tests were performed at +45° and -45°, with the infill alternating between these two single directions.  In contrast, the blue system uses a continuously rotating pattern of +45° applied to each successive layer in order to ensure homogeneous distribution of heat as well as offering more angles to much better more geometries or to have a more agnostic perspective and not be part topology dependent or the part being affected by it.

### Process Control

Process Control monitors the continuity between the deposition head and the substrate. When continuity is lost, the system **automatically increases material flow** to restore contact. Combining **accurate Process Control** with Meltio design guidelines ensures **reliable, high-quality prints** and fully leverages the potential of wire-based DED.

#### Common Activation Scenarios

- Excessively **high energy density** (wire melts before reaching the melt pool)
- Incorrect or increasing **working distance**  (wire melts before reaching the melt pool)
- **Excessive overhangs** in the print geometry

#### Solutions

- Reduce energy density: lower laser power (decrease deposition rate) or **increase Print Speed (increase deposition rate)**
- Use the **Working Distance Wizard** and adjust **Material Flow Rate**
- Evaluate and adapt the **design for Meltio AM** capabilities

#### Testing Without Process Control

During the first phase of material optimization, we recommend **deactivating Process Control** to confirm process reliability. If the energy density is too high, the print will fail due to lack of wire continuity—this ensures that the process itself is stable without relying on correction mechanisms and allows to find the top of the process window, focusing on reducing porosity adjusting the energy density (lower part of the process window). Once stability is achieved, Process Control can be re-enabled to help with overhangs or non-standard geometries.

# Hotwire Integration (Advanced)

Once the initial print parameters are optimized, **Hotwire** can be introduced for further improvements. It is not recommended to use Hotwire from the beginning due to process unpredictability.

**Electrical Settings (Based on Joule Effect)**

The effect varies by material conductivity, greater resistance greater effect (e.g., greater in stainless steels like 316L, minimal in copper).

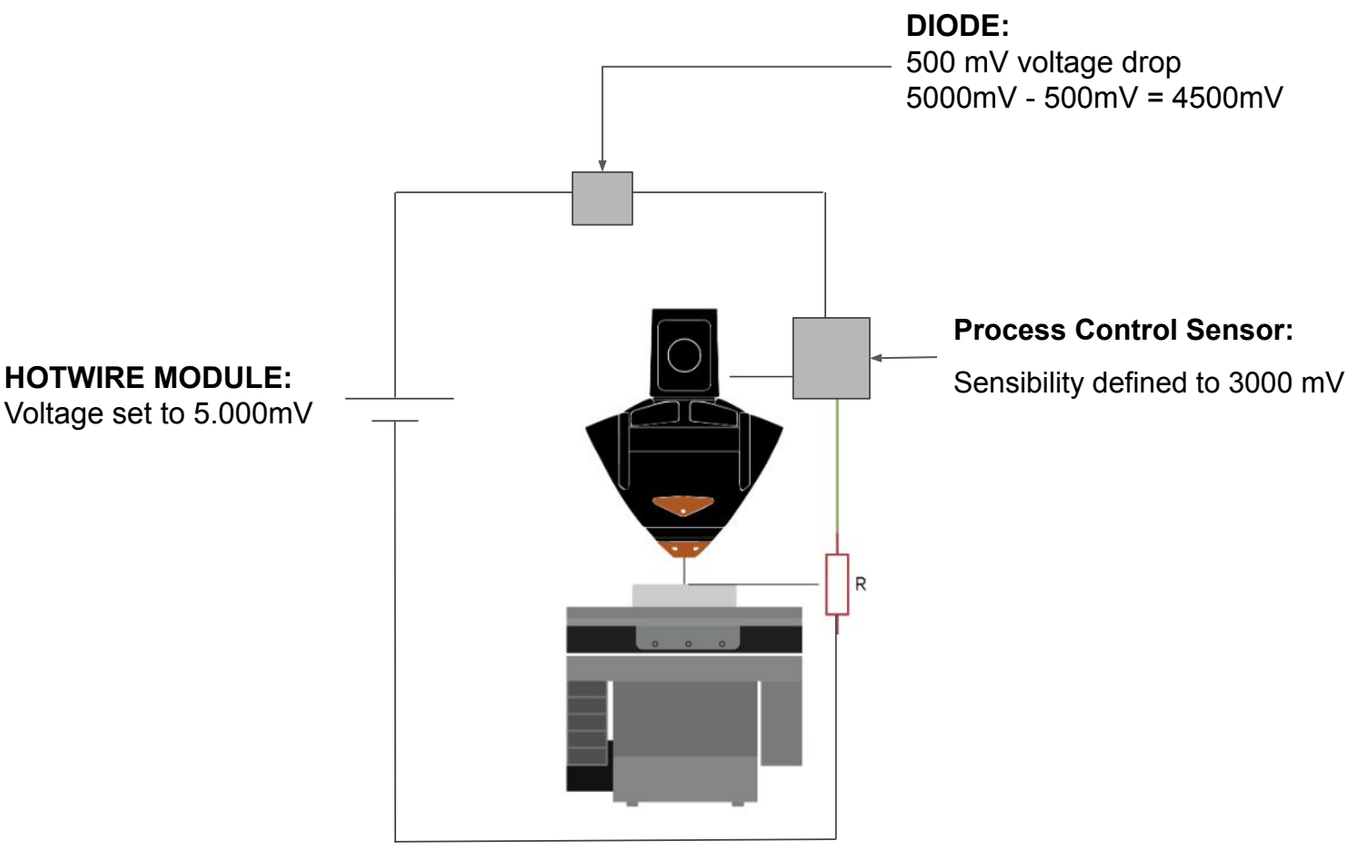
- **Hotwire Current:** 0–75 A
  - Minimum effective: 20 A
  - High values may overheat the wire, leading to instability and Process Control Activations.

- **Hotwire Voltage:** 3500–6000 mV
  - **Recommended:** 5000–6000 mV
  - <3500 mV may prevent current ramp-up.
  - 6000 mV or more may destabilize the system and interfere with Process Control (which operates around 5000 mV).

**Process Control Mode**

- **Without Hotwire:** Use **Automatic Current Mode**
- **With Hotwire:** Use **Voltage Mode**

  - Default sensitivity: **3000 mV**
  - Can be adjusted depending on material and stability following the above guidelines.



When wire is touching substrate, voltage ins close to 0mV, with this the total power generated through joules effect can be calculated but no cannot be measured if it is applied in the melt pool or along a larger distance or are/volume. When wire lase contact with substrate, the voltage the process control sensor will read would be 4500mV and  0 Amperage of Hotwire, activating the process control routine feeding extra wire.

Process control sensibility should be always smaller than Hotwire voltage - diode voltage drop including an extra offset of 1000mV approx. In this illustration the lowest sensibility for process control should be  3500mV

# Energy Density Formules

As previously mentioned, the energy density is a parameter that relates the volume of material deposited to a defined energy input. The unit for energy density is Jules / mm^3.Please note that energy density values are not extrapolable within different materials as they have different laser absorption and behavior. Also the formula does not consider all the physical properties of the material being printed but offer an approachable way of characterizing the materials.

## Meltio M450 and M600:

Due to the Volumetric Material Calculation that happens directly in the slicing software, we need to recalculate the material volume. Use the following formula to calculate the energy density:

$$\frac{\text{Laser Power (W)}}{\text{Layer Height (mm)} \times \text{Deposition Width (mm)} \times \frac{\text{Print Speed (mm/min)}}{60}} = \text{Energy Density (J/mm}^3\text{)}$$

## Meltio Engine:

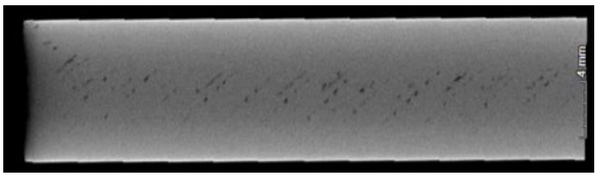
Calculating the energy density for the Meltio Engine is easier as the wire feed-rate is a direct input parameter. Here the material volume is calculated using wire feed-rate and the wire diameter.

$$\frac{\text{Laser Power (W)}}{\text{Wire Feedrate (mm/s)} \times \pi \times \text{Wire Radius (mm)}^2} = \text{Energy Density (J/mm}^3\text{)}$$

# Process Bands

### Interpretation of Results

When Interpreting the results of the aforementioned study we find that we can group our parts into three different Process Bands based on the energy density they were produced with: Lack of Fusion, Minor Defects and Fully Dense Parts.

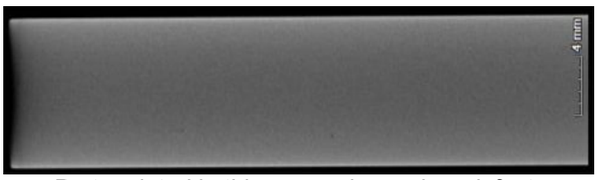


*Typical Defect Pattern for parts that show “Lack of Fusion”.*

**1: High Speed & Lack of Fusion**

*Low Energy Density*

Parts printed within this range of energy densities can be produced at the highest speed but with serious defects, often containing multiple long linear indications of lack of fusion. Use parameters within this band for printing parts quickly when mechanical properties are not of importance. Beware that due to the large sizes, defects may appear visible to the naked eye after machining.



*Parts printed in this range show minor defects.*

**2: Medium Speed & Minor Defects**

*Medium Energy Density*

Parts printed in this range generally do not show defects that are visible to the naked eye and perform well mechanically. Defect size is generally smaller than 250 microns but may affect fatigue life of the component adversely.

*Defect-Free Build using High Energy Density.*

**3: Fully Dense Parts**

*High Energy Density*

Parts printed in this region do not show any defects that can be detected using CT Scanning. Density measurements beyond this point must be performed using metallography. We find that parts in this region typically show densifications greater than 99.99%. This however comes at the price of print speed which is typically much lower.

***Note:*** *The results and classification of process bands are based purely on the described methodology and only serve as guidance for the easy selection of applications dependent process parameters.*

# Meltio Materials Characterization Methodology

## Characterization Development Phases for Solid parts

### Blue System

Meltio qualifies materials through a structured, step-by-step process divided into four phases, designed to identify optimal printing parameters and validate the material's performance for industrial applications **using the Meltio Blue system**.

**Phase 0** serves as a **preliminary stage** in which the general **printability of the material** is evaluated. This includes verifying the stability of the melt pool, assessing arc behavior, and ensuring the wire feedability and compatibility with Meltio's system. If the material proves printable under basic conditions, it proceeds to the qualification workflow.

**Phase 1** is divided into **two stages: Test A and Test B**. In this phase, a wide range of parameter sets is tested using **CT scanning** and **hardness measurements** to evaluate **bulk density**. The primary goal is to identify parameter sets that meet the requirements of the **NASA-STD-6030** standard. Any parameters that fail to deliver macroscopically dense builds are discarded.

**Phase 2** uses the selected parameter from the previous phase to fabricate **larger preforms** intended for the extraction of **tensile** and **metallographic samples**. During this phase, **heat treatments** are applied to optimize the **mechanical properties** of the material. The goal is to assess and refine the material's mechanical performance under standardized conditions. At the end of this phase, comprehensive data is collected, allowing for the creation of a detailed **material datasheet**.

**Phase 3** involves validating the chosen parameter through **impact or fatigue testing** on large preforms. Additional analyses, such as **chemical composition checks**, are carried out to confirm the material's consistency and reliability.

Below are the main steps required to successfully complete each phase of the qualification process.

## Verification Process for Optimal Parameter Selection and Material Density

This section describes the process verification system, both the Meltio infrared and the Meltio Blue systems, for parameter selection, in order to identify the ones that provide the best relative density.

Samples are built using simple geometries (Phases 1), from which by-products are extracted to perform defect analysis and classify the different energy density bands. For the acceptance of these samples, they must demonstrate high densification in the printed parts.

This information allows users of the Meltio systems to select the most efficient process to achieve the target material quality.

## Verification Process

The verification system depends on the Meltio system being used:

**Blue System**:

The process verification consists of two steps: the first is an analysis using penetrant liquids to detect surface defects in the samples, and the second involves performing micrography on the samples to assess defect size and material density (based on NASA-STD-6030 standards).

The sample dimensions are **250mm*250mm*30mm (X*Y*Z)**, and we extract 6 specimens of **30mm*60mm*30mm (X*Y*Z)** for penetrant liquid testing and micrography.

According to the standard, the porosity should be less than 0.25% of the volume in 6cm², with pore sizes under 100 microns. The full results of the material testing process can be found in the material data sheets for each of the Meltio materials.

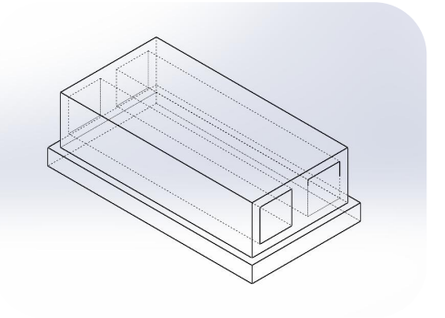
# Characterization Phases - Blue System

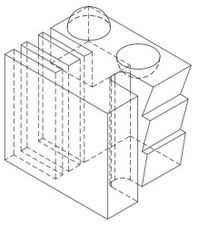
## Phase 0 - Printability

A large range of parameters are tested to define the process window.

Preform Size: 15mm x 30mm x 60mm

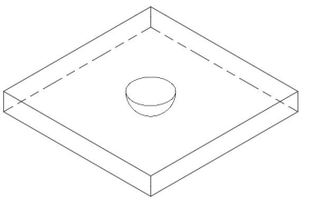
Varied Parameters: Layer Height, Laser Power, Print Speed, Flow Rate





Test A

Test B



## Phase 1 - Bulk Density

Subselection of best results from phase 0 we build sufficient samples for statistically significant testing for each of parameter set.

TestA
Preform Size: 67mm x 50mm x 70mm
Tested Attributes:
- Liquid penetrant test

Test B
Preform Size: 250mm x 250mm x 30mm
Number of samples: 6

Tested Attributes:
- Density
- Micrography
- Metallography

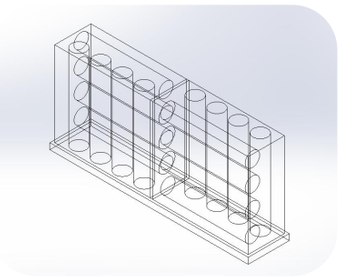
## Phase 2 - Structural Properties

Once the phase 1 parameters were accepted, we constructed sufficient samples to perform statistically significant tests for each set of parameters.

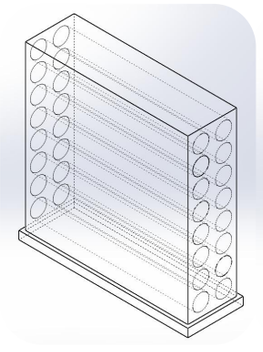
Preform Size: 95mm x 155mm x 55mm
Preform Cut Size: 30mm x 155mm x 55mm
Sample Size: M4 cylindrical (UNE EN ISO 6892-1)
Number of samples: 16 samples in two directions, 8 horizontal and 8 vertical per block.
Printing Direction: XY

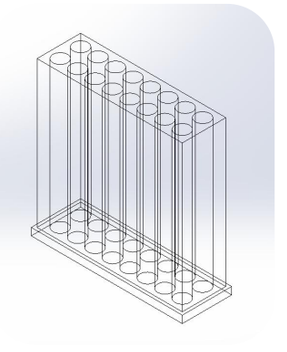
Tested Attributes:
- Density
- Hardness post Heat Treatment
- Tensile Strength
- Metallography

Preform Size



Preform Cut Size





## Phase 3 - Advanced Properties

Selection of best parameter set from phase 2. Advanced tests are carried out based on the material.

Preform Size: 30 mm x 100mm x 100mm
Sample Size: Depending on the test (ASTM)
Number of samples: From 16 to 40.
Printing Direction: XY and XZ

Tested Attributes:

- Fatigue Testing
- Impact Testing
- Chemical Analysis
- RDX testing

# Meltio Materials Characterization Methodology

## Characterization Development Phases for Solid parts

### Infrared System (Legacy)

Meltio qualifies materials through a step-by-step approach, **exclusively designed for the Meltio Infrared Printing System**, divided into three phases with the goal of identifying the optimal printing parameters.

**Phase 1:** In this initial phase, a wide range of parameter sets is tested using computed tomography (CT) and hardness measurements to estimate bulk density. All parameter sets that do not result in macroscopically dense builds are discarded.

**Phase 2:** The top three parameter sets from Phase 1 are selected to produce larger preforms. These preforms are used to extract samples for tensile testing and metallographic analysis. Heat treatments are applied during this phase as required. By the end of Phase 2, sufficient data is gathered to generate a preliminary material datasheet.

**Phase 3:** The best parameter set identified in Phase 2 is used to produce large preforms for impact or fatigue testing. Additional evaluations, such as chemical composition analysis, are conducted to verify the final properties of the material.

## Verification Process for Optimal Parameter Selection and Material Density

This section describes the process verification system, both the Meltio infrared and the Meltio Blue systems, for parameter selection, in order to identify the ones that provide the best relative density.

Samples are built using simple geometries (Phases 1), from which by-products are extracted to perform defect analysis and classify the different energy density bands. For the acceptance of these samples, they must demonstrate high densification in the printed parts.

This information allows users of the Meltio systems to select the most efficient process to achieve the target material quality.

## Verification Process

The verification system depends on the Meltio system being used:

**Infrared System**:

The verification of the printing process involves CT scan analysis of a large number of samples to ensure good part density.

The printed samples have dimensions of **60mm*30mm*15mm (X*Y*Z)**, from which two specimens of 1**0mm*50mm*10mm (X*Y*Z)** are extracted for CT scan analysis.

CT scans are performed at a resolution of 24 microns per pixel by an external laboratory. The full results of the material testing process can be found in the material data sheets for each of the Meltio materials.

# Characterization Phases - Infrared System

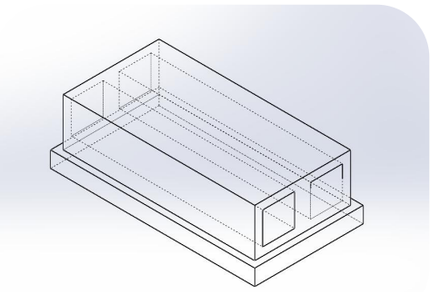
## Phase 1 - Bulk Density

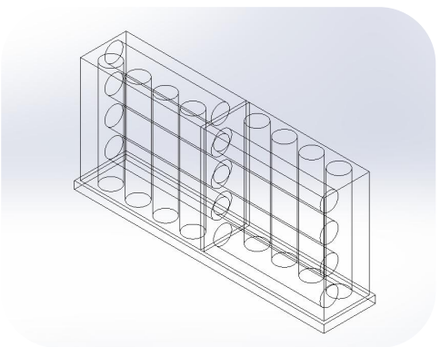
A large range of parameters are tested to define the process window.

Preform Size: 15mm x 30mm x 60mm
Sample Size: 10mm x 10 mm x 60mm
Number of samples: 10

Varied Parameters: Layer Height, Laser Power, Print Speed, Flow Rate

Tested Attributes:
- Density
- Hardness





## Phase 2 - Basic Properties

Subselection of best results from phase 1 we build sufficient samples for statistically significant testing for each of parameter set.

Preform Size: 30mm x 160mm x 70mm
Sample Size: M10 cylindrical (UNE EN ISO 6892-1)
Number of samples: 48
Printing Direction: XY and XZ

Tested Attributes:
- Density
- Hardness post Heat Treatment
- Tensile Strength
- Metallography

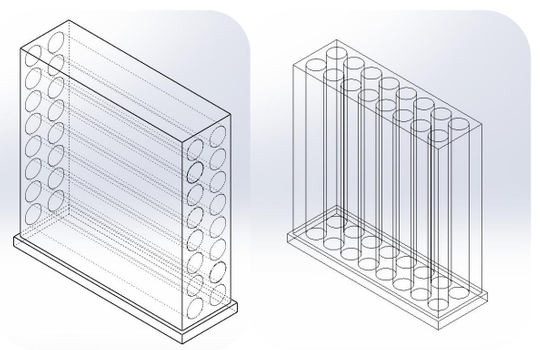
## Phase 3 - Advanced Properties

Selection of best parameter set from phase 2. Advanced tests are carried out based on the material.

Preform Size: 30 mm x 100mm x 100mm
Sample Size: Depending on the test (ASTM)
Number of samples: From 16 to 40.
Printing Direction: XY and XZ

Tested Attributes:

- Fatigue Testing
- Impact Testing
- Chemical Analysis
- RDX testing



# Meltio Materials Characterization Methodology

## Characterization Development Phases for Hollow parts

### Blue System

Meltio characterizes hollow profiles using a cylindrical geometry with a **diameter of 80 mm and a height of 150 mm**. This geometry was specifically selected to determine the optimal printing parameters.

This approach ensures that the geometry of the hollow cylinder, which presents specific challenges such as **thermal gradients and wall stability**, can be reliably manufactured with consistent material quality and dimensional accuracy using the Meltio system.

- The profile of **a single perimeter** profile is optimized for single thin-walled cylinders and validated for cylinders with 80 mm diameter and larger diameter geometries. In smaller parts—where the enclosed area or perimeter length is reduced—thermal accumulation may to happen. To prevent overheating, a minimum cooling time per layer is applied. For example, if the layer is completed in 20 seconds, but the minimum time defined per layer is 25 seconds, a 5-second pause is automatically inserted to adjust the time to the minimum layer time and prevent overheating in smaller areas. If the layer time is longer than the minimum layer time, no pause is applied.
- The **double perimeter** profile has also been developed to meet the requirements of applications that require greater wall thickness. It is optimized to improve the bond between passes and increase structural strength, while maintaining control over roundness and internal diameter.
- Geometries that use **three or more perimeters** are considered **solid profiles**, as they allow the use of infill between perimeters. These profiles follow a different parameterization strategy focused on controlling material deposition and internal structure..

At Meltio, hollow profiles are printed using maximum laser power, as they are optimized for high deposition rate, ensuring complete fusion of the material. The parameters are defined based on the thermal and geometric behavior of each material, paying special attention to the aspect ratio (AR), that is., the ratio between the height and width of the deposition.

The parameterization strategy is based on the following key considerations:

- **Deposition height and width:** The height and width of the deposited bead depend directly on the fluidity and thermal conductivity of the material. Increased energy input increases both the height and width of the bead, altering the resulting Aspect ratio. For example, stainless steel produces thick lines and requires slower printing speeds to maintain stability.
    - **Lines of height and width** are typically formed in materials with high viscosity or low thermal conductivity.
    - **Aspect ratio (AR) (Height / Width)** values typically range from 0.20 to 0.36, depending on the material and energy input. To obtain these values, the layer height is divided by the layer width. For example, the profile of a single wall of 316LSi has an aspect ratio of 0.2424, with a deposition height of 1.2 mm and a deposition width of 4.95 mm.
- **Base Print Speed**: Base print speed: The base print speed is selected together with the line dimensions to ensure stable and uniform deposition. The speed must be adjusted according to the observed quality of the part:
    - If you can observe material hanging, also known as “hairs,” on the print surface, it means that not enough energy is being transferred to the material; the profile speed should be reduced to match the material's needs.
    - If a wave pattern appears on the surface, which does not look completely horizontal to the layers, it indicates excess energy; the speed should be increased.

  In addition, using slower speeds with higher bead heights and widths allows for increased deposition rates, as the heat retained in the printed part promotes better fusion and flow of the material.
- **Cooldown Time per Layer**: Cooldown time is critical for materials sensitive to thermal accumulation. For example, titanium for hollow 1 perimeter profile may require up to 60 seconds of cooling between layers to prevent overheating and ensure geometric fidelity.

  This strategy also considers part size. The hollow cylinder profile is designed for geometries of 80 mm in diameter or greater. When printing smaller hollow profiles—either in enclosed area or length—the risk of heat accumulation increases. To mitigate this, a **minimum cooldown per layer** is applied:

    - For instance, if a geometry is set with a 25-second cooldown per layer but the actual layer time is only 20 seconds, an additional 5-second pause is added.
    - Conversely, if a geometry takes 35 seconds to complete, no cooldown is applied, as sufficient time has already elapsed during printing.
    - When the geometry has two perimeters or more, waiting times are reduced because performing the two perimeters maintains greater process stability.

## Characterization Development Phases for Hollow parts for Blue Laser 1.4kW

The following table shows the parameters of the official profiles for one perimeter and for two perimeters available in our official Slicers Meltio Horizon and Meltio Space. These profiles are continuously developed and improved, so they may be subject to change in the future.

| 1 Perimeters | | | | | | |
|---|---|---|---|---|---|---|
| Material | Revision | Deposition Height (mm) | Deposition Width (mm) | Base Print Speed (mm/s) | Cooldown (sec) | Aspect ratio (Height / Width) |

# Introduction to Post-Processing and Heat-Treatment

## Introduction

Heat treatment is a process of heating and cooling metals or alloys to alter their physical and mechanical properties without changing their shape. The objective of heat treatment is to improve the material's performance, durability, and strength.
There are various types of heat treatment processes, including annealing, normalizing, tempering, quenching, etc. Each process involves heating the metal to a specific temperature, holding it at that temperature for a specific time, and then cooling it at a controlled rate.

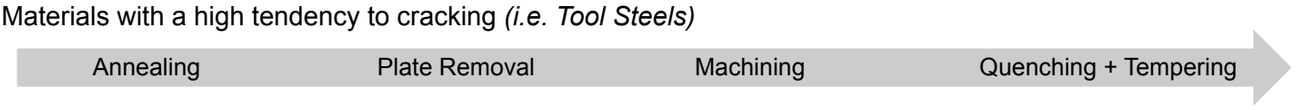
## Heat treatment applications

Heat treatment is not always mandatory, but it can be essential to achieve the desired properties and performance of a metal or alloy. In many cases, heat treatment is required to meet specific design or performance requirements.
For example, some metal alloys used in high-stress applications, such as aircraft parts or critical machine components, require heat treatment to improve their strength and durability. Similarly, some manufacturing processes may require heat treatment to relieve stresses, reduce distortion, or improve machinability.
However, there may be cases where heat treatment is not necessary or may even be detrimental to the metal's properties. Therefore, the decision to perform heat treatment depends on the specific material, its intended use, and the desired properties.

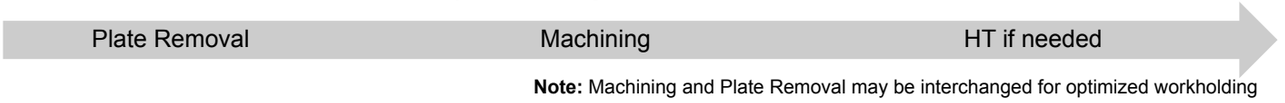
## Process order of heat treatments

The heat treatment is carried out depending on its purpose. If the heat treatment is required in order to machine the material (stress relieve), it will always be carried out after the printing process and before removing the piece from the base plate, this is the case of hard steels (H11 tool steel) to avoid cracking during machining. On the other hand, if the heat treatment serves to improve the mechanical properties of the material, it will generally be carried out after removing the piece from the base plate and before the final machining process, this is the case of Ti64 or Inconel 718.

Materials with a high tendency to cracking *(i.e. Tool Steels)*



Materials with a low to Medium tendency to cracking *(i.e. Ti64 or 316L)*



**Note:** Machining and Plate Removal may be interchanged for optimized workholding

## Equipment

The equipment used for heat treatment depends on the type of heat treatment process and the size and shape of the material being treated. Usually, the most common are a furnace to heat the material to a certain temperature and a quenching tank for cooling the material rapidly. More complex heat treatments are typically outsourced to service providers.

## Cost of heat treatments

The cost of heat treatment depends on various factors, including the type of heat treatment, the size and shape of the part, the material being treated and the quantity of parts being treated.
Generally, the larger the part size, the higher the cost of heat treatment. This is because larger parts require more time and energy to heat and cool, which increases the operating costs of the equipment. Also, larger parts require bigger facilities and ovens which are less common, driving up the cost.

Moreover, the cost of heat treatment can also vary depending on the type of heat treatment process being used. For example, annealing and normalizing are typically less expensive than quenching and tempering, which require more specialized equipment and materials.
In addition, the material being treated can also affect the cost of heat treatment. Some materials may require longer heating and cooling times or more specialized equipment, which can increase the cost.
Therefore, it is important to consider all these factors when estimating the cost of heat treatment for a specific part or batch of parts.

** Please note that the following chart is intended to provide a simplified overview of the heat treatment process. While the information presented is generally accurate, it is important to recognize that actual heat treatment processes can vary depending on a range of factors, including the specific materials involved, the equipment used, and the desired outcomes. As such, the information presented should be used for educational purposes only and should not be relied upon as a definitive guide to the heat treatment process in all cases. It is recommended that you consult with a qualified professional or refer to more detailed technical resources for specific information on heat treatment processes applicable to your situation.*

# Study of thermal cycles effect for CNC post-processing

This study evaluates the influence of three different cooling conditions — Room temperature (reference), air cooled, and water cooled (quenching with cutting fluid) — of an additive manufactured part on its hardness and derived mechanical properties.

The following study uses 17-4PH stainless steel as a representative metal, as it is a precipitation hardening alloy of the martensitic family. In additive manufacturing (AM) processes, especially those involving high thermal gradients and rapid solidification, the properties as printed are greatly influenced by the cooling conditions that occur immediately after deposition. The cooling method applied plays a fundamental role in determining the final microstructure, hardness and mechanical performance of the material.

**Sample Dimensions:**

This experiment was carried out using 3 samples of 30 × 30 × 90 mm prints, a single type of cooling was applied to each sample throughout its manufacture.
Each sample is produced in 3 steps of 30x30x30, after each step cooled down is applied, then a face of the cube is machined to allow the hardness test to be performed on said face. More information on the effect of the different cooling methods on the next page or section.

**Cooling Conditions:**

**1- Controlled cooling, cooled down naturally at room temperature,** (reference condition) yielded the **highest hardness (398 HV)**. This is attributed to a more complete martensitic transformation and a homogeneous distribution of fine precipitates. Under this condition, the material exhibited **high yield strength and tensile strength**, but **low ductility**. The dense microstructure with minimal retained austenite favors load-bearing capacity and structural rigidity.

**2- Air cooling with compressed air on a CNC machine during 7 minutes**, producing an **intermediate hardness (387 HV)** and mechanical behavior that balances strength and ductility. The slower cooling rate can lead to the presence of retained austenite or coarser precipitates, slightly lowering the resistance to plastic deformation. However, it improves **elongation** and **impact resistance**.

**3- Quenching with cutting fluid on a CNC machine during 30 seconds** on a CNC machine resulted in the **lowest hardness (365 HV)**, due to less efficient martensitic transformation and potential formation of soft phases such as retained austenite. The material displayed **medium-low strength** but **increased ductility**, offering improved deformation capacity under cyclic or dynamic loads.

The cooling method directly affects not only hardness but also the internal stress state, phase distribution, and mechanical reliability of the printed or heat-treated part. The data confirms the following relationship between cooling rate and mechanical behavior:

- **Controlled Cooling (398 HV)**: High strength, low ductility → Recommended for rigid, load-bearing parts.
- **Air Cooling (387 HV)**: Balanced strength and toughness → Recommended for components requiring both resistance and flexibility.
- **Cutting Fluid Cooling (365 HV)**: Lower strength, high ductility → Recommended for flexible, fatigue-tolerant applications.

In conclusion, the **selection of the cooling strategy** for 17-4PH stainless steel should be aligned with the specific functional requirements of the component. **Controlled cooling** is optimal for applications requiring high hardness and structural integrity, while **air or fluid quenching** offers viable alternatives where **ductility, energy absorption, or resistance to cyclic loading** are more critical. Proper control of the cooling phase is essential to tailor the final properties of 17-4PH and ensure its performance in demanding industrial environments.

# Study of thermal cycles effect for CNC post-processing

**How this affects printing on a hybrid system?**

In hybrid systems that combine additive and subtractive processes in the same configuration, the type of cooling can significantly influence material performance. Inadequate cooling management could lead to unexpected contraction or high levels of residual stress, which in turn can cause the printed part to become more fragile.

**How it affects tool wear?**

Cooling conditions during printing influence surface hardness and residual stress distribution, which in turn affect tool wear in the subtractive phase:

- Higher hardness surfaces (as in controlled cooling) are more resistant to cutting, increasing tool load and wear rate, especially for high-speed or dry machining.
- Lower hardness surfaces (as in cutting fluid-cooled parts) are easier to machine and reduce tool wear, but may also produce gummy or ductile chips, potentially affecting chip evacuation and surface finish.

**What Meltio recommends?**

The cooling strategy applied during metal additive manufacturing has a direct impact on the microstructure, mechanical properties and reliability of the final component. It also influences process efficiency and tool wear in hybrid systems. Based on operational experience and thermal studies, Meltio recommends:

- Avoid using liquid refrigerants during printing. Abrupt and uncontrolled cooling can cause incomplete microstructural transformations, soft phases, internal stresses, and negatively affect material quality. This is not the most recommended option when seeking the best mechanical properties, but it is the one that allows for the fastest cooling of the material for subsequent machining and reduces tool wear..
- Cooling to room temperature between layers or sections. This strategy allows for gradual heat dissipation, promoting controlled and uniform solidification. It usually results in components with greater hardness, structural strength and less deformation, making it particularly suitable for parts subjected to static or structural loads.
- The use of compressed air or fan as an intermediate option. This solution is particularly useful in hybrid systems where more active thermal dissipation is required to protect tools or reduce cycle time. Air-assisted cooling provides a balance between mechanical strength and ductility, making it suitable for parts that must absorb impacts or load cycles

Maintain a consistent and controlled thermal strategy throughout the process, especially in step or segmented printing. Proper thermal management improves material reproducibility, reduces the risk of distortion, and optimises tool life in hybrid systems.

MELTIO
